

# Continuous logic for the classical logician

C. L. C. L. Polymath

ABSTRACT. Let  $\mathcal{L}$  be a first-order two-sorted language. In general, very little model theory is possible if we restrict to structures that have the form  $\langle M, R \rangle$  for some fixed  $R$ . But not everything is lost when  $R$  is a compact topological space. Continuous logic deals with this case. Rivisiting old ideas we present a back-to-basics approach to continuous logic.

## 1. Introduction

As a minimal motivating example, consider a real vector space  $M$ . This is among the most simple structures considered in model theory. Now, expand it by adding a norm. A norm is a function that, given vector, outputs a real number. We may formalize this in a natural way by using a two-sorted structure  $\langle M, \mathbb{R} \rangle$ . Now, we have two conflicting aspirations

- i. to apply the basic tools of model theory (such as elementarity, compactness, and saturation);
- ii. to stay within the realm of normed spaces (hence insist that  $\mathbb{R}$  should remain  $\mathbb{R}$  throughout).

These two requests are blatantly incompatible, something has to give. Different people have attempted different paths.

1. Nonstandard analysts happily embrace norms that take values in some  ${}^*\mathbb{R} \geq \mathbb{R}$ . These normed spaces are nonstandard, but there are tricks to transfer results from nonstandard to standard normed spaces and vice versa. Model theorists, when confronted with similar problems, have used similar approaches (in more generality and with different notation).
2. Henson and Iovino propose to stick to the standard notion of norm but restrict the notion of elementarity and saturation to a smaller class of formulas (which here is denoted by  $\mathbb{H}$ ). They demonstrate that many standard tools of model theory apply in their setting. The work of Henson and Iovino is focussed on Banach spaces and has hardly been applied to broader contexts. See [1] for a survey.
3. Real valued logicians take the most radical approach. They abandon classical true/false valued logic in favour of a logic valued in the interval  $[0, 1]$ . Unfortunately, this adds notational burden and restricts the class of structures that can be considered. See [2] for a survey.

We elaborate on the ideas of Henson and Iovino and generalize them to a larger class of structures. We restrict the notions of elementarity and saturation. But we use a class of formulas  $\mathbb{I}$  which is larger than  $\mathbb{H}$ . Though  $\mathbb{I}$  has approximatively the same expressive power as  $\mathbb{H}$  (cf. Propositions 21 and 22), it is evident (cf. Example 3) that  $\mathbb{I}$  is more convenient to use.

We also borrow intuitions and results from nonstandard analysis to an extent that we could claim the title: nonstandard analysis for the standard logician.

## 2. A class of structures

Let  $\mathcal{R}$  be some fixed first-order structure which is endowed with a Hausdorff compact topology (in particular, a normal topology). The language  $L_{\mathcal{R}}$  contains relation symbols for the compact subsets  $C \subseteq \mathcal{R}^n$  and a function symbol for each continuous functions  $f : \mathcal{R}^n \rightarrow \mathcal{R}$ . In particular, there is a constant for each

element of  $R$ . According to the context,  $C$  and  $f$  denote either the symbols of  $L_R$  or their interpretation in the structure  $R$ .

**Definition 1.** Let  $L_M$  be a one-sorted (first-order) language. By **model** we mean an  $\mathcal{L}$ -structure of the form  $\mathcal{M} = \langle M, R \rangle$ , where  $M$  ranges over  $L_M$ -structures, while  $R$  is the structure above. We use  $M$  and  $R$  to denote the two sorts of  $\mathcal{L}$ . The language  $\mathcal{L}$  is an expansion of both  $L_M$  and  $L_R$ . The new symbols allowed in  $\mathcal{L}$  are function symbols of sort  $M^n \rightarrow R$ .

In some examples we need to replace the sort  $M$  with many sorts  $M_1 \dots, M_k$ . In this case the language  $L_M$  is replaced with  $L_{M_1 \dots, M_k}$ , the language that governs the structure  $\langle M_1 \dots, M_k \rangle$ . Models have the form  $\langle M_1 \dots, M_k, R \rangle$ . The new symbols in the language  $\mathcal{L}$  are of sort  $M_1^{n_1} \dots, M_k^{n_k} \rightarrow R$ .

The notion of model will be (inessentially) restricted once the monster model is introduced, in Section 7.

Clearly, saturated  $\mathcal{L}$ -structures exist but, with the exception of trivial cases (i.e. when  $R$  is finite), they are not models in the sense of Definition 1. As a remedy, below we carve out a set of formulas  $L \subseteq \mathbb{I} \subseteq \mathcal{L}$ , such that every model has an  $\mathbb{I}$ -elementary,  $\mathbb{I}$ -saturated extension that is also a model.

Warning: as usual  $L_R$ ,  $L_M$ , and  $\mathcal{L}$  denote both first-order languages and the corresponding set of formulas. The symbols  $\mathbb{I}$  and  $\mathbb{H}$  defined below denote only sets of  $\mathcal{L}$ -formulas.

**Definition 2.** Formulas in  $\mathbb{I}$  are defined inductively from two sorts of  **$\mathbb{I}$ -atomic** formulas

- i. formulas of the form  $t(x; y) \in C$ , where  $C \subseteq R^n$  is compact (in the product topology) and  $t(x, y)$  is a  $n$ -tuple of terms of sort  $M^{|x|} \times R^{|y|} \rightarrow R$ ;
- ii. all formulas in  $L_M$ .

We require that  $\mathbb{I}$  is closed under the Boolean connectives  $\wedge, \vee$ ; the quantifiers  $\forall^M, \exists^M$  of sort  $M$ ; and the quantifiers of sort  $R$  which are denoted by  $\forall^R, \exists^R$ .

We write  $\mathbb{H}$  for the set of formulas in  $\mathbb{I}$  without quantifiers of sort  $R$ .

Formulas in  $\mathbb{H}$  are a generalization of the positive bounded formulas of Henson and Iovino. Here we also introduce the larger class  $\mathbb{I}$  because it offers some advantages. For instance, it is easy to see (cf. Example 3 for a hint) that  $\mathbb{I}$  has at least the same expressive power as real valued logic (in fact, it is way more expressive<sup>1</sup>). Somewhat surprisingly, we will see (cf. Propositions 21 and 22) that the formulas in  $\mathbb{I}$  can be approximated by formulas in  $\mathbb{H}$ .

**Example 3.** Let  $R = [0, 1]$ , the unit interval in  $\mathbb{R}$ . Let  $t(x)$  be a term of sort  $M^{|x|} \rightarrow R$ . Then there is a formula in  $\mathbb{I}$  that says  $\sup_x t(x) = \tau$ . Indeed, consider the formula

$$\forall^M x [t(x) \div \tau \in \{0\}] \quad \wedge \quad \forall^R \varepsilon \left[ \varepsilon \in \{0\} \vee \exists^M x [\tau \div (t(x) + \varepsilon) \in \{0\}] \right]$$

which, in a more legible form, becomes

$$\forall^M x [t(x) \leq \tau] \quad \wedge \quad \forall^R \varepsilon > 0 \exists^M x [\tau \leq t(x) + \varepsilon].$$

We conclude this introduction with a question. Is it possible extend the theory exposed below to a larger  $\mathcal{L}$ ? E.g. can we allow in  $\mathcal{L}$  function symbols of sort  $M^n \times R^m \rightarrow R$  with both  $n$  and  $m$  positive? These would have natural interpretations, e.g. when  $M$  is a group acting on a compact set  $R$ .

<sup>1</sup>This unsubstantiated claim should be interpreted as a conjecture. A painstaking technical comparison with real valued logic is not in the scope of this introductory exploratory paper.

### 3. The standard part

In this section we recall the notion of the standard part of an element in an elementary extension of a compact Hausdorff topological space. Our goal is to prove Lemma 8 which in turn is required for the proof of the compactness theorem. The reader that is willing to accept the compactness theorem without proof may skip this section.

Let  $R \leq {}^*R$ . For each  $\beta \in R$  we define the type

$$m_\beta(x) = \{x \in D : D \text{ compact neighborhood of } \beta\}.$$

The set of the realizations of  $m_\beta(x)$  in  ${}^*R$  is known to nonstandard analysts as the monad of  $\beta$ . The following fact is well-known.

**Fact 4.** For every  $\alpha \in {}^*R$  there is a unique  $\beta \in R$  such that  $\alpha \models m_\beta(x)$ .

*Proof.* Negate the existence of  $\beta$ . For every  $\gamma \in R$  pick some compact neighborhood  $D_\gamma$  of  $\gamma$ , such that  ${}^*R \models \alpha \notin D_\gamma$ . By compactness there is some finite  $\Gamma \subseteq R$  such that  $D_\gamma$ , with  $\gamma \in \Gamma$ , cover  $R$ . By elementarity these  $D_\gamma$  also cover  ${}^*R$ . A contradiction. The uniqueness of  $\beta$  follows from normality.  $\square$

We denote by  $\text{st}(\alpha)$  the unique  $\beta \in R$  such that  $\alpha \models m_\beta(x)$ . We write  $\alpha \approx \alpha'$  if  $\text{st}(\alpha) = \text{st}(\alpha')$ .

**Fact 5.** For every  $\alpha \in {}^*R$  and every compact  $C \subseteq R$

$${}^*R \models \alpha \in C \rightarrow \text{st}(\alpha) \in C.$$

*Proof.* Assume  $\text{st}(\alpha) \notin C$ . By normality there is a compact set  $D$  disjoint from  $C$  that is a neighborhood of  $\text{st}(\alpha)$ . Then  ${}^*R \models \alpha \in D \subseteq \neg C$ .  $\square$

**Fact 6.** For every  $\alpha \in ({}^*R)^{|x|}$  and every function symbol  $f$  of sort  $R^{|x|} \rightarrow R$

$${}^*R \models \text{st}(f(\alpha)) = f(\text{st}(\alpha)).$$

*Proof.* By Fact 4 and the definition of  $\text{st}(-)$  it suffices to prove that  ${}^*R \models f(\alpha) \in D$  for every compact neighborhood  $D$  of  $f(\text{st}(\alpha))$ .

Fix one such  $D$ . Then  $\text{st}(\alpha) \in f^{-1}[D]$ . By continuity  $f^{-1}[D]$  is a compact neighborhood of  $\text{st}(\alpha)$ . Therefore  ${}^*R \models \alpha \in f^{-1}[D]$  and, as  $R \leq {}^*R$  we obtain  ${}^*R \models f(\alpha) \in D$ .  $\square$

Let  ${}^*\mathcal{M} = \langle M, {}^*R \rangle$  be an  $\mathcal{L}$ -structure such that  $R \leq {}^*R$ . The **standard part of  ${}^*\mathcal{M}$**  is the model  $\mathcal{M} = \langle M, R \rangle$  that interprets the symbols  $f$  of sort  $M^n \rightarrow R$  as the functions

$$f^{\mathcal{M}}(a) = \text{st}(f^{{}^*\mathcal{M}}(a)) \quad \text{for all } a \in M^n.$$

Symbols in  $L_M$  maintain the same interpretation.

**Fact 7.** Let  ${}^*\mathcal{M}$  and  $\mathcal{M}$  be as above. Let  $t(x; y)$  be a term of sort  $M^{|x|} \times R^{|y|} \rightarrow R$ . Then for every  $a \in M^{|x|}$  and  $\alpha \in ({}^*R)^{|y|}$

$$t^{\mathcal{M}}(a; \text{st}(\alpha)) = \text{st}(t^{{}^*\mathcal{M}}(a; \alpha))$$

*Proof.* When a  $t$  is function symbol of sort  $M^{|x|} \rightarrow R$ , the claim holds by definition. When  $t$  is a function symbol of sort  $R^{|y|} \rightarrow R$ , the claim follows from Fact 6. Now, assume inductively that

$$t_i^{\mathcal{M}}(a; \text{st}(\alpha)) = \text{st}(t_i^{{}^*\mathcal{M}}(a; \alpha))$$

holds for the terms  $t_1(x; y), \dots, t_n(x; y)$  and let  $t = f(t_1, \dots, t_n)$  for some function  $f$  of sort  $R^n \rightarrow R$ . Then the claim follows immediately from the induction hypothesis and Fact 6.  $\square$

**Lemma 8.** Let  ${}^*\mathcal{M}$  and  $\mathcal{M}$  be as above. Then for every  $\varphi(x; y) \in \mathbb{I}$ ,  $a \in M^{|x|}$  and  $\alpha \in ({}^*R)^{|y|}$

$${}^*\mathcal{M} \models \varphi(a; \alpha) \Rightarrow \mathcal{M} \models \varphi(a; \text{st}(\alpha))$$

*Proof.* Suppose  $\varphi(x; y)$  is  $\mathbb{I}$ -atomic. If  $\varphi(x; y)$  is a formula of  $L_{\mathcal{M}}$  the claim is trivial. Otherwise  $\varphi(x; y)$  has the form  $t(x; y) \in C$ . Assume that the tuple  $t(x; y)$  consists of a single term. The general case follows easily from this special case. Assume that  ${}^*\mathcal{M} \models t(a; \alpha) \in C$ . Then  $\text{st}(t({}^*\mathcal{M}(a; \alpha)) \in C$  by Fact 5. Therefore  $t^{\mathcal{M}}(a; \text{st}(\alpha)) \in C$  follows from Fact 7. This proves the lemma for  $\mathbb{I}$ -atomic formulas. Induction is immediate.  $\square$

#### 4. Henson-Iovino approximations

For  $\varphi, \varphi' \in \mathbb{I}(M)$  (free variables are hidden) we write  $\varphi' > \varphi$  if  $\varphi'$  is obtained by replacing each atomic formula of the form  $t \in C$  occurring in  $\varphi$  with  $t \in C'$  where  $C'$  is some compact neighborhood of  $C$ . If no such atomic formulas occur in  $\varphi$ , then  $\varphi > \varphi$ . We also have  $\varphi > \varphi$  when  $\varphi = (t \in C)$  for some clopen set  $C$ . Note that  $>$  is a dense (pre)order of  $\mathbb{I}(M)$ . Formulas in (i) of Definition 2 do not occur under the scope of a negation, therefore we always have that  $\varphi \rightarrow \varphi'$ .

We write  $\tilde{\varphi} \perp \varphi$  when  $\tilde{\varphi}$  is obtained by replacing each atomic formula  $t \in C$  occurring in  $\varphi$  with  $t \in \tilde{C}$  where  $\tilde{C}$  is some compact set disjoint from  $C$ . Moreover the  $\mathbb{I}$ -atomic formulas in  $L_{\mathcal{M}}$  are replaced with their negation and each connective is replaced with its dual i.e.,  $\vee, \wedge, \exists, \forall, \exists^R, \forall^R$  are replaced with  $\wedge, \vee, \forall, \exists, \forall^R, \exists^R$  respectively. We say that  $\tilde{\varphi}$  is a **strong negation** of  $\varphi$ . It is clear that  $\tilde{\varphi} \rightarrow \neg\varphi$ .

**Lemma 9.** For all  $\varphi \in \mathbb{I}(M)$

1. for every  $\varphi' > \varphi$  there is a formula  $\tilde{\varphi} \perp \varphi$  such that  $\varphi \rightarrow \neg\tilde{\varphi} \rightarrow \varphi'$ ;
2. for every  $\tilde{\varphi} \perp \varphi$  there is a formula  $\varphi' > \varphi$  such that  $\varphi \rightarrow \varphi' \rightarrow \neg\tilde{\varphi}$ .

*Proof.* If  $\varphi \in L$  the claims are obvious. Suppose  $\varphi$  is of the form  $t \in C$ . Let  $\varphi'$  be  $t \in C'$ , for some compact neighborhood of  $C$ . Let  $O$  be an open set such that  $C \subseteq O \subseteq C'$ . Then  $\tilde{\varphi} = (t \in R \setminus O)$  is as required by the lemma. Suppose instead that  $\tilde{\varphi}$  is of the form  $t \in \tilde{C}$  for some compact  $\tilde{C}$  disjoint from  $C$ . By the normality of  $R$ , there is  $C'$ , a compact neighborhood of  $C$  disjoint from  $\tilde{C}$ . Then  $\varphi' = (t \in C')$  is as required. The lemma follows easily by induction.  $\square$

For  $p(x) \subseteq \mathbb{I}(A)$ , we write

$$p'(x) = \{ \varphi'(x) : \varphi' > \varphi \text{ for some } \varphi(x) \in p \}$$

in particular  $\{\varphi(x)\}' = \{ \varphi'(x) : \varphi' > \varphi \}$ .

#### 5. Morphisms

Let  $\mathcal{M} = \langle M, R \rangle$  and  $\mathcal{N} = \langle N, R \rangle$  be two models. We say that a partial map  $f : M \rightarrow N$  is  **$\mathbb{I}$ -elementary** if for every  $\varphi(x) \in \mathbb{I}$  and every  $a \in (\text{dom } f)^{|x|}$

1.  $\mathcal{M} \models \varphi(a) \Rightarrow \mathcal{N} \models \varphi(fa)$ .

An  $\mathbb{I}$ -elementary map that is total is called an  **$\mathbb{I}$ -elementary embedding**. We write  $\mathcal{M} \leq^{\mathbb{I}} \mathcal{N}$  and say that  $\mathcal{M}$  is an  **$\mathbb{I}$ -elementary submodel** of  $\mathcal{N}$ .

The definitions of  **$\mathbb{H}$ -elementary** map/embedding/submodel is obtained replacing  $\mathbb{I}$  by  $\mathbb{H}$ .

As  $\mathbb{I}$  and  $\mathbb{H}$ -elementary maps are in particular  $L_M$ -elementary, they are injective. However, their inverse need not be  $\mathbb{I}$ , respectively  $\mathbb{H}$ -elementary. In other words the converse implication in (1) may not hold. We have chosen to work with the classical notion of satisfaction at the cost of this asymmetric notion of elementarity. This contrast with the approach of Henson and Iovino. They introduce the notion of *approximated satisfaction*. The approximated  $\mathbb{H}$ -morphisms we define below are the maps that preserve Henson-Iovino approximated satisfaction. These morphisms are invertible, cf. Fact 10.

We say that the map  $f : M \rightarrow N$  is **approximately  $\mathbb{I}$ -elementary** if for every formula  $\varphi(x) \in \mathbb{I}$ , and every  $a \in (\text{dom } f)^{|x|}$

$$\mathcal{M} \models \{\varphi(a)\}' \Rightarrow \mathcal{N} \models \{\varphi(fa)\}'.$$

We define **approximately  $\mathbb{H}$ -elementary** maps in the same manner. We leave to the reader to verify (using Lemma 9) that  $\mathbb{I}$ -elementarity implies its approximated version, similarly for  $\mathbb{H}$ -elementarity. We will see (Proposition 14) that with a slight amount of saturation also the converse holds. Finally, under full saturation, all differences disappear as all these morphisms becomes  $\mathcal{L}$ -elementarity maps (Corollary 20).

However, the following holds in general.

**Fact 10.** If  $f : M \rightarrow N$  is approximately  $\mathbb{I}$ -elementary then

$$\mathcal{M} \models \{\varphi(a)\}' \Leftrightarrow \mathcal{N} \models \{\varphi(fa)\}'.$$

for every  $\varphi(x) \in \mathbb{I}$ , and every  $a \in (\text{dom } f)^{|x|}$ . The same holds for approximately  $\mathbb{H}$ -elementary maps.

*Proof.* Only implication  $\Leftarrow$  requires a proof. Assume the r.h.s. of the equivalence. Fix  $\varphi' > \varphi$  and prove  $\mathcal{M} \models \varphi'(a)$ . Let  $\varphi' > \varphi'' > \varphi$ . By Lemma 9 there is some  $\tilde{\varphi} \perp \varphi''$  such that  $\varphi'' \rightarrow \neg \tilde{\varphi} \rightarrow \varphi'$ . Then  $\mathcal{N} \models \neg \tilde{\varphi}(fa)$  and therefore  $\mathcal{M} \models \neg \tilde{\varphi}(a)$ . Then  $\mathcal{M} \models \varphi'(a)$ .  $\square$

Finally, we introduce the morphisms that corresponds to the classical partial isomorphisms. We say that  $f : M \rightarrow N$  is a **partial  $\mathbb{I}$ -embedding** if implication (1) holds for all  $\mathbb{I}$ -atomic formulas  $\varphi(x)$

**Fact 11.** If  $f : M \rightarrow N$  is a partial  $\mathbb{I}$ -embedding then

$$\mathcal{M} \models \varphi(a) \Leftrightarrow \mathcal{N} \models \varphi(fa)$$

for every  $a \in (\text{dom } f)^{|x|}$  and every  $\mathbb{I}$ -formulas  $\varphi(x)$  without quantifiers of sort  $M$ .

*Proof.* The equivalence is trivial for formulas in  $L_M$  so we only consider  $\mathbb{I}$ -atomic formulas as in (i) of Definition 1. Implication  $\Rightarrow$  holds by definition. Vice versa, if  $\mathcal{M} \models t(a) \notin C$  then, by normality,  $\mathcal{M} \models t(a) \in \tilde{C}$  for some compact  $\tilde{C}$  disjoint of  $C$ . By the definition of  $\mathbb{I}$ -embedding,  $\mathcal{N} \models t(a) \in \tilde{C}$ . Hence  $\mathcal{N} \models t(a) \notin C$ . Induction is immediate.  $\square$

## 6. Compactness

It is convenient to distinguish between consistency with respect to models and consistency with respect to  $\mathcal{L}$ -structures. We say that a theory  $T$  is  **$\mathcal{L}$ -consistent** when  $\mathcal{M} \models T$  for some  $\mathcal{L}$ -structure  $\mathcal{M}$ . We say that  $T$  is **consistent** when  $\mathcal{M}$  is required to be a model.

**Theorem 12.** Let  $T \subseteq \mathbb{I}$  be finitely consistent. Then  $T$  is consistent.

*Proof.* Suppose  $T$  is finitely consistent (or finitely  $\mathcal{L}$ -consistent, for that matter). By the classical compactness theorem  $^*\mathcal{M} \models T$  for some  $\mathcal{L}$ -structure  $^*\mathcal{M} = \langle M, ^*R \rangle$ . Let  $\mathcal{M} = \langle M, R \rangle$  be the standard part of  $^*\mathcal{M}$  as defined in Section 3. Then  $\mathcal{M} \models T$  by Lemma 8.  $\square$

A model  $\mathcal{N}$  is  $\lambda$ - $\mathbb{I}$ -saturated if it realizes all types  $p(x; y) \subseteq \mathbb{I}(\mathcal{N})$  with fewer than  $\lambda$  parameters that are finitely consistent in  $\mathcal{N}$ . When  $\lambda = |\mathcal{N}|$  we simply say  $\mathbb{I}$ -saturated. The existence of  $\mathbb{I}$ -saturated models is obtained from the classical case just as for Theorem 12.

**Theorem 13.** Every model has an  $\mathbb{I}$ -elementary extension to a saturated model (possibly of inaccessible cardinality).

The following proposition shows that a slight amount of saturation tames the  $\mathbb{I}$ -formulas.

**Proposition 14.** Let  $\mathcal{N}$  be an  $\omega$ - $\mathbb{I}$ -saturated model. Then

$$\{\varphi(x; y)\}' \leftrightarrow \varphi(x; y)$$

holds in  $\mathcal{N}$  for every formula  $\varphi(x; y) \in \mathbb{I}(\mathcal{N})$ .

*Proof.* We prove  $\rightarrow$ , the non trivial implication. The claim is clear for atomic formulas. Induction for conjunction, disjunction and the universal quantifiers is immediate. We consider case of the existential quantifiers of sort  $\mathbf{M}$ . The case of existential quantifiers of sort  $\mathbf{R}$  is identical. Assume inductively

$$\text{ih.} \quad \{\varphi(x, z; y)\}' \rightarrow \varphi(x, z; y)$$

We need to prove

$$\{\exists^{\mathbf{M}} z \varphi(x, z; y)\} \rightarrow \exists^{\mathbf{M}} z \varphi(x, z; y)$$

From (ih) we have

$$\exists^{\mathbf{M}} z \{\varphi(x, z; y)\} \rightarrow \exists^{\mathbf{M}} z \varphi(x, z; y)$$

Therefore it suffices to prove

$$\{\exists^{\mathbf{M}} z \varphi(x, z; y)\}' \rightarrow \exists^{\mathbf{M}} z \{\varphi(x, z; y)\}'$$

Replace  $x, y$  with some parameters, say  $a, \alpha$  and assume the antecedent, that is, the truth of the theory  $\{\exists^{\mathbf{M}} z \varphi'(a, z; \alpha) : \varphi' > \varphi\}$ . We need to prove the consistency of the type  $\{\varphi'(a, z; \alpha) : \varphi' > \varphi\}$ . By saturation, finite consistency suffices. This is clear if we show that the antecedent is closed under conjunction. Indeed it is easy to verify that if  $\varphi_1, \varphi_2 > \varphi$  then  $\varphi_1 \wedge \varphi_2 > \varphi'$  for some  $\varphi' > \varphi$ . In words, the set of approximations of  $\varphi$  is a directed set.  $\square$

**Remark 15.** The proposition above will be frequently used in this form. If evaluated in an  $\omega$ - $\mathbb{I}$ -saturated model,  $p'(x)$  is equivalent to  $p(x)$ .

A consequence of the proposition above is that between  $\omega$ - $\mathbb{I}$ -saturated models the approximated morphisms defined in Section 5 coincide with their unapproximated version. In particular, following follows from Fact 10.

**Corollary 16.** Let  $\mathcal{M}$  be a model that is  $\omega$ - $\mathbb{I}$ -saturated for some  $\lambda \geq |\mathcal{L}|$ . Let  $f : M \rightarrow N$  be an  $\mathbb{I}$ -elementary map. Then

$$\mathcal{M} \models \varphi(a) \Leftrightarrow \mathcal{N} \models \varphi(fa)$$

for every  $\mathbb{I}$ -atomic formula  $\varphi(x)$  and every  $a \in (\text{dom } f)^{|x|}$ .

## 7. The monster model

We denote by  $\mathcal{U} = \langle U, R \rangle$  some large  $\mathbb{I}$ -saturated structure which we call the **monster model**. For convenience we assume that the cardinality of  $\mathcal{U}$  is an inaccessible cardinal which we denote by  $\kappa$ . Truth is

evaluated in  $\mathcal{U}$  unless otherwise is specified. Below we say **model** for  $\mathbb{I}$ -elementary submodel of  $\mathcal{U}$ . We stress once again that the truth of some  $\varphi \in \mathbb{I}(M)$  in a model  $\mathcal{M}$  (only) implies the truth of  $\varphi$  (in  $\mathcal{U}$ ). If also the converse implication holds we say  $\mathcal{M}$  a **strong model**. By Corollary 16 the  $\omega$ - $\mathbb{I}$ -saturated models are strong models. Also Cauchy complete models, which we will introduce below, are strong models.

Let  $A \subseteq U$  be a small set throughout this section. We define a topology on  $U^{|x|} \times R^{|y|}$  which we call the  **$\mathbb{I}(A)$ -topology**. The closed sets of this topology are the sets defined by the types  $p(x; y) \subseteq \mathbb{I}(A)$ . This is a compact topology by the  $\mathbb{I}$ -compactness Theorem 12. The following fact demonstrate how  $\mathbb{I}$ -compactness applies in this context. There are some subtle differences from the classical setting.

**Fact 17.** Let  $p(x) \subseteq \mathbb{I}(A)$  be a type. Then for every  $\varphi(x) \in \mathbb{I}(U)$

1. if  $p(x) \rightarrow \neg\varphi(x)$  then  $\psi(x) \rightarrow \neg\varphi(x)$  for some  $\psi(x)$  conjunction of formulas in  $p(x)$ ;
2. if  $p(x) \rightarrow \varphi(x)$  and  $\varphi' > \varphi$  then  $\psi(x) \rightarrow \varphi'(x)$  for some conjunction of formulas in  $p(x)$ .

*Proof.* Claim (1) is immediate by saturation. Claim (2) follows from the first by Lemma 9.  $\square$

When  $A \subseteq U$ , we write  **$S_{\mathbb{I}}(A)$**  for the set of types

$$\mathbb{I}\text{-tp}(a/A) = \{\varphi(x) : \varphi(x) \in \mathbb{I}(A) \text{ such that } \varphi(a)\}$$

as  $a$  ranges over the tuples of elements of  $U$ . We write  **$S_{\mathbb{I},x}(A)$**  when the tuple of variables  $x$  is fixed. The same notation applies also with  $\mathbb{H}$  for  $\mathbb{I}$ .

The following proposition will be strengthened by Corollary 20 below.

**Proposition 18.** The types  $p(x) \in S_{\mathbb{I}}(A)$  are maximally consistent subsets of  $\mathbb{I}_x(A)$ . That is, for every  $\varphi(x) \in \mathbb{I}(A)$ , either  $\varphi(x) \in p$  or  $p(x) \rightarrow \neg\varphi(x)$ . The same holds with  $\mathbb{H}$  for  $\mathbb{I}$ .

*Proof.* Let  $p(x) = \mathbb{I}\text{-tp}(a/A)$  and suppose  $\varphi(x) \notin p$ . Then  $\neg\varphi(a)$ . From Lemma 9 and Proposition 14 we obtain

$$\neg\varphi(x) \rightarrow \bigvee_{\tilde{\varphi} \perp \varphi} \tilde{\varphi}(x).$$

Hence  $\tilde{\varphi}(a)$  holds for some  $\tilde{\varphi} \perp \varphi$  and  $p(x) \rightarrow \neg\varphi(x)$  follows.  $\square$

## 8. Approximate elimination of quantifiers of sort $\mathbf{R}$

We show that the quantifiers  $\forall^{\mathbf{R}}$  and  $\exists^{\mathbf{R}}$  can be eliminated up to some approximation.

**Proposition 19.** The monster model (or any saturated model, for that matter) is  $\mathbb{H}$ -homogeneous, that is, every  $\mathbb{H}$ -elementary map  $f : U \rightarrow U$  of cardinality  $< \kappa$  extends to an automorphism.

*Proof.* By Proposition 18, the inverse of an  $\mathbb{H}$ -elementary map  $f : U \rightarrow U$  is  $\mathbb{H}$ -elementary. Then the usual proof by back-and-forth applies.  $\square$

As promised, we strengthen Proposition 18. Let  $A \subseteq U$  be a small set throughout this section.

**Corollary 20.** Let  $p(x) \in S_{\mathbb{H}}(A)$ . Then  $p(x)$  is complete for formulas in  $\mathcal{L}_x(A)$ . That is, for every  $\varphi(x) \in \mathcal{L}(A)$ , either  $p(x) \rightarrow \varphi(x)$  or  $p(x) \rightarrow \neg\varphi(x)$ . Clearly, the same holds for  $p'(x)$ .

*Proof.* If  $b \models p(x) = \mathbb{H}\text{-tp}(a/A)$  then there is an  $\mathbb{H}$ -elementary map  $f \supseteq \text{id}_A$  such that  $fa = b$ . As  $f$  extends to an automorphism and every automorphism is  $\mathcal{L}$ -elementary, the corollary follows.  $\square$

For  $a, b \in U^{|x|}$  we write  $a \equiv_A b$  if  $a$  and  $b$  satisfy the same  $\mathcal{L}$ -formulas over  $A$ , bearing in mind that formulas in  $\mathbb{H}(A)$  or  $\mathbb{I}(A)$  suffices to test the equivalence.

In the classical setting, from an equivalence between types one derives an equivalence between formulas. Without negation, this is not true. Still, we can infer an approximate form of equivalence. Next proposition show that formulas in  $\mathbb{I}(A)$  are approximated by formulas in  $\mathbb{H}(A)$ .

**Proposition 21.** Let  $\varphi(x) \in \mathbb{I}(A)$ . For every given  $\varphi' > \varphi$  there is some formula  $\psi(x) \in \mathbb{H}(A)$  such that  $\varphi(x) \rightarrow \psi(x) \rightarrow \varphi'(x)$ .

*Proof.* By Corollary 20 and Remark 15

$$\neg\varphi(x) \rightarrow \bigvee_{p'(x) \rightarrow \neg\varphi(x)} p'(x)$$

where  $p(x)$  ranges over  $\mathcal{S}_{\mathbb{H},x}(A)$ . By Fact 17 and Lemma 9

$$\neg\varphi(x) \rightarrow \bigvee_{\neg\tilde{\psi}(x) \rightarrow \neg\varphi(x)} \neg\tilde{\psi}(x),$$

where  $\tilde{\psi}(x) \in \mathbb{H}(A)$ . Equivalently,

$$\varphi(x) \leftarrow \bigwedge_{\tilde{\psi}(x) \leftarrow \varphi(x)} \tilde{\psi}(x).$$

By compactness, see Fact 17, for every  $\varphi' > \varphi$  there are some finitely many  $\tilde{\psi}_i(x) \in \mathbb{H}(A)$  such that

$$\varphi'(x) \leftarrow \bigwedge_{i=1,\dots,n} \tilde{\psi}_i(x) \leftarrow \varphi(x)$$

which yields the interpolant required by the proposition.  $\square$

We also need an approximation result for the negation of formulas in  $\mathbb{I}(A)$ .

**Proposition 22.** Let  $\varphi(x) \in \mathbb{I}(A)$  be such that  $\neg\varphi(x)$  is consistent. Then  $\psi'(x) \rightarrow \neg\varphi(x)$  for some consistent  $\psi(x) \in \mathbb{H}(A)$  and some  $\psi' > \psi$ .

*Proof.* Let  $a \in U^{|x|}$  be such that  $\neg\varphi(a)$ . Let  $p(x) = \mathbb{H}\text{-tp}(a/A)$ . By Corollary 20,  $p'(x) \rightarrow \neg\varphi(x)$ . By compactness  $\psi'(x) \rightarrow \neg\varphi(x)$  for some  $\psi' > \psi \in p(x)$ .  $\square$

## 9. The Tarski-Vaught test and the Löwenheim-Skolem theorem

The following proposition is not literally the Tarski-Vaught test because it only applies when the larger structure is the master model.

**Proposition 23.** Let  $M$  be a subset of  $U$ . Then the following are equivalent

1.  $M$  is the domain of a model  $\mathcal{M} = \langle M, R \rangle$ ;
2. for every formula  $\varphi(x) \in \mathbb{H}(M)$ 

$$\exists^M x \varphi(x) \Rightarrow \text{for every } \varphi' > \varphi \text{ there is an } a \in M \text{ such that } \varphi'(a);$$
3. for every formula  $\varphi(x) \in \mathbb{I}(M)$ 

$$\exists^M x \neg\varphi(x) \Rightarrow \text{there is an } a \in M \text{ such that } \neg\varphi(a).$$

*Proof.* (1 $\Rightarrow$ 2) Assume  $\exists^M x \varphi(x)$  and let  $\varphi' > \varphi$  be given. By Lemma 9 there is some  $\tilde{\varphi} \perp \varphi$  such that  $\varphi(x) \rightarrow \neg\tilde{\varphi}(x) \rightarrow \varphi'(x)$ . Then  $\neg\forall^M x \tilde{\varphi}(x)$  hence, by (1),  $\mathcal{M} \models \neg\forall^M x \tilde{\varphi}(x)$ . Then  $\mathcal{M} \models \neg\tilde{\varphi}(a)$  for some  $a \in M$ . Hence  $\mathcal{M} \models \varphi'(a)$  and  $\varphi'(a)$  follows from (1).

(2 $\Rightarrow$ 3) Assume (2) and let  $\varphi(x) \in \mathbb{I}(M)$  be such that  $\exists^M x \neg \varphi(x)$ . By Corollary 22, there are a consistent  $\psi(x) \in \mathbb{H}(M)$  and some  $\psi' > \psi$  such that  $\psi'(x) \rightarrow \neg \varphi(x)$ . Then (3) follows.

(3 $\Rightarrow$ 1) Assume (3). By the classical Tarski-Vaught test  $M \leq U$ . Let  $\mathcal{M} = \langle M, R \rangle$  be the unique  $\mathcal{L}$ -structure that is a substructure of  $\mathcal{U}$ . Then  $\varphi(a) \Leftrightarrow \mathcal{M} \models \varphi(a)$  holds for every  $\mathbb{I}$ -atomic formula  $\varphi(x)$  and for every  $a \in M^{|x|}$ . Now, assume inductively

$$\mathcal{M} \models \varphi(a, b) \Rightarrow \varphi(a, b).$$

Using (3) and the induction hypothesis we prove by contraposition that

$$\mathcal{M} \models \forall^M y \varphi(a, y) \Rightarrow \forall^M y \varphi(a, y).$$

Indeed,

$$\begin{aligned} \neg \forall^M y \varphi(a, y) &\Rightarrow \exists^M y \neg \varphi(a, y) \\ &\Rightarrow \neg \varphi(a, b) && \text{for some } b \in M^{|y|} \\ &\Rightarrow \mathcal{M} \models \neg \varphi(a, b) && \text{for some } b \in M^{|y|} \\ &\Rightarrow \mathcal{M} \not\models \forall^M y \varphi(a, y). \end{aligned}$$

Induction for the connectives  $\vee, \wedge, \exists^M, \exists^R$ , and  $\forall^R$  is straightforward.  $\square$

Classically, the main application of the Tarski-Vaught test is in the proof of the downward Löwenheim-Skolem Theorem. Note that here the classical downward Löwenheim-Skolem Theorem holds in full for all  $\mathcal{L}$ -structures. In particular every  $A \subseteq U$  is contained in a model of cardinality  $|\mathcal{L}(A)|$ . However, in some cases we can do better than that.

The **weight** of  $\mathcal{L}$ , which we denote by  $\text{wgt}(\mathcal{L})$  is the minimal cardinality of a set of formulas  $\mathbb{H}'$  such that for every  $\varphi, \varphi'' \in \mathbb{H}$  such that  $\varphi'' > \varphi$  there is a  $\varphi' \in \mathbb{H}'$  such that  $\varphi'' > \varphi' > \varphi$ . It is not difficult to see that when  $R$  is the real unit interval and  $\mathcal{L}$  contains at most countably many symbols of sort  $M^n \rightarrow R$  then  $\text{wgt}(\mathcal{L}) = \omega$ .

**Proposition 24.** Let  $A \subseteq U$ . Then  $A$  is contained in a model of cardinality at most  $\text{wgt}(\mathcal{L}) + |A|$ .

*Proof.* As in the classical Löwenheim-Skolem Theorem, using (2) of Proposition 23.  $\square$

## 10. Cauchy complete models

For  $t(x, z)$  a term of sort  $M^{|x|+|z|} \rightarrow R$  and  $D \subseteq R^2$  we define the formula

$$x \sim_{t,D} y = \forall^M z \langle t(x, z), t(y, z) \rangle \in D$$

If  $t(x, z) = t_1(x, z), \dots, t_n(x, z)$  is a tuple of terms  $x \sim_{t,D} y$  denotes the conjunction of the formulas  $x \sim_{t_i,D} y$ . As  $D$  ranges over the compact neighborhoods of the diagonal  $\Delta \subseteq R^2$  and  $t(x, z)$  ranges over the finite tuples parameter-free terms, the formulas  $x \sim_{t,D} y$  define a system of entougages on  $U^{|x|}$ . We refer to the topology associated as the **R-topology**. It is not difficult to verify that the R-topology on  $U^{|x|}$  coincides with the product of the R-topology on  $U$ . We define two equivalent types

$$\begin{aligned} x \sim_R y &= \left\{ x \sim_{t,\Delta} y : t(x, z) \text{ parameter-free term} \right\}. \\ x \sim'_R y &= \left\{ x \sim_{t,D} y : t(x, z) \text{ parameter-free term, } D \text{ compact neighborhood of } \Delta \right\}. \end{aligned}$$

Again, it is easy to verify that if  $|x| = |y| = \lambda$  then  $x \sim_R y$  if and only if  $x_i \sim_R y_i$  for every  $i < \lambda$ .

We say that  $p(x) \subseteq \mathbb{I}(U)$  is **R-invariant** if  $x \sim_R y \rightarrow [p(x) \leftrightarrow p(y)]$ . We say that  $p(x)$  is a **Cauchy type** if it is consistent and  $p(x) \wedge p(y) \rightarrow x \sim_R y$ .

We say that a type  $q(x)$  is finitely satisfiable in  $M$  if every conjunction of formulas in  $q(x)$  has a solution in  $M$ . This definition is classical, but note that when  $q(x)$  is over  $M$  we can only infer that  $q'(x)$  is finitely satisfiable.

**Lemma 25.** Let  $\mathcal{M}$  be a model. Then the following are equivalent

1.  $p(x) \subseteq \mathbb{I}(M)$  is an R-invariant Cauchy type;
2.  $p(x) \leftrightarrow a \sim_R x$  for some/any  $a \models p(x)$ .
3.  $a \sim'_R x$  is finitely satisfiable in  $M$  for some/any  $a \models p(x)$ .

*Proof.* (1 $\Rightarrow$ 2) Let  $a \models p(x)$ . Substituting  $a$  for  $y$  in the definition of Cauchy type we obtain  $p(x) \rightarrow a \sim_R x$ . Similarly, from the definition of R-invariance we obtain  $a \sim_R x \rightarrow p(x)$ .

(2 $\Rightarrow$ 3) By compactness, as  $p'(x)$  is finitely satisfiable in  $M$ .

(3 $\Rightarrow$ 1) Let  $a_{t,D} \in M$  be a realization of  $a \sim_{t,D} x$  as  $D$  ranges over the compact neighborhoods of the diagonal and  $t(x, z)$  over the finite tuples parameter-free terms. Then, by the uniqueness of the limit, the type  $p(x)$  containing the formulas  $x \sim_{t,D} a_{t,D}$  is as required by the lemma.  $\square$

Let  $\mathcal{M}$  be a model. We say that  $\mathcal{M}$  is **Cauchy complete** if every R-invariant Cauchy type  $p(x) \subseteq \mathbb{I}(M)$  is realized in  $\mathcal{M}$ . Note that if  $p(x)$  is Cauchy type then any consistent type  $q(x)$  containing  $p(x)$  is also Cauchy. In particular the type  $p(x) \cup \mathbb{I}\text{-Th}(\mathcal{U}/M)$  is Cauchy. The following trivial consequence is worth to be noted

**Remark 26.** Cauchy complete models are strong models. I.e.,  $\mathcal{M} \models \varphi$  for every true  $\varphi \in \mathbb{I}(M)$ .

**Fact 27.** Let  $\mathcal{M}$  be a model that is  $\lambda$ - $\mathbb{I}$ -saturated for some  $\lambda > |\mathcal{L}|$ . Then  $\mathcal{M}$  is Cauchy complete.

*Proof.* Let  $p(x) \subseteq \mathbb{I}(M)$  be an R-invariant Cauchy type. Pick any  $a \models p(x)$ . For every formula  $\varphi(x)$  in the type  $a \sim_R x$  and every  $\varphi' > \varphi$  pick some  $\psi(x) \in p$  such that  $\psi(x) \rightarrow \varphi'(x)$ . There are at most  $|\mathcal{L}|$  such formulas  $\psi(x)$ . By saturation they have a common solution  $b$  in  $M$ . Then  $b \sim_R a$  and, by invariance,  $b \models p(x)$ .  $\square$

## 11. Example: metric spaces

We discuss a simple example. Let  $M, d$  is a metric space. Let  $L_M$  contain symbols only for continuous functions  $M^n \rightarrow M$ . The language  $\mathcal{L}$  has also a symbol  $d$  for a function of sort  $M^2 \rightarrow R$ . Let  $R = \mathbb{R} \cup \{\pm\infty\}$ , with the topology that makes it homeomorphic to the unit interval. Let  $\mathcal{M} = \langle M, R \rangle$  be the structure that interprets the symbols of the language as natural.

Let  $\mathcal{U}$  be a monster model,  $\mathcal{M} \preceq^{\mathbb{I}} \mathcal{U}$ . Clearly,  $d$  does not define a metric on  $U$  as there are pairs of elements at infinite distance. However, when restricted to a ball of finite radius,  $d$  defines a pseudometric on  $U$ . Therefore the notion of convergent sequence makes perfectly sense in  $U$ .

**Fact 28.** Let  $\mathcal{U}$  be as above. Then for every model  $\mathcal{N} = \langle N, R \rangle$  the following are equivalent for every  $a \in U$

1.  $p(x) = \mathbb{I}\text{-tp}(a/N)$  is a Cauchy type;
2. there is a sequence  $\langle a_i : i \in \omega \rangle$  of elements of  $N$  that converges to  $a$ .

*Proof.* First note that, by the continuity of the terms with respect to the metric,  $a \sim_R b$  is equivalent to  $d(a, b) = 0$ .

(2 $\Rightarrow$ 1) Let  $\langle \varepsilon_i : i \in \omega \rangle$  be a sequence of reals that converges to 0 and such that  $d(a_i, a) \leq \varepsilon_i$  for every  $i \in \omega$ . Then the formulas  $d(a_i, x) \leq \varepsilon_i$  are in  $p(x)$ . Then every element realizing  $p(x)$  is at distance 0 from  $a$ . Therefore  $p(x) \rightarrow a \sim_{\mathbb{R}} x$ .

(1 $\Rightarrow$ 2) As  $p(x)$  is Cauchy type,  $p(x) \rightarrow a \sim_{\mathbb{R}} x$ . Then  $p'(x) \rightarrow d(a, x) < 2^{-i}$  for all  $i$ . By compactness (see Fact 17) there are formulas  $\varphi_i(x) \in p$  such that  $\varphi'_i(x) \rightarrow d(a, x) < 2^{-i}$  for some  $\varphi'_i > \varphi_i$ . By  $\mathbb{I}$ -elementarity there is an  $a_i \in N$  such that  $\varphi'_i(a_i)$ . As  $d(a, a_i) < 2^{-i}$  for all  $i$ , the sequence  $\langle a_i : i \in \omega \rangle$  converges to  $a$ .  $\square$

### Garbage after this point

Let  $t(x, y)$  and  $D$  be a term of sort  $\mathbf{M}^{|x|+|z|} \rightarrow \mathbf{R}$ , respectively a compact neighborhood of the diagonal. For  $\gamma, \xi \in \text{Aut}(\mathcal{U})$  and  $a$  a finite tuple of elements of  $\mathbf{M}$  we write  $\gamma \sim_{a,t,C} \xi$  for  $\gamma a \sim_{a,t,D} \xi a$ . This defines a system of entourages on  $\text{Aut}(\mathcal{U})$ .

By  $\text{Aut}(\mathcal{U}/\{M\})$  we denote the set of automorphisms of  $\mathcal{U}$  that fix  $M$  setwise. When  $\text{Aut}(\mathcal{U}/\{M\})$  is dense in  $\text{Aut}(\mathcal{U})$  with respect to the topology above, we say that  $\mathcal{M}$  is **approximatively  $\omega$ -homogeneous**. Note that this is the classical notion of homogeneity only with the discrete topology replaced by the  $\mathbf{R}$ -topology.

We write  $\mathbb{I}_{\forall}$  for the set of  $\mathbb{I}$ -formulas where the quantifier  $\exists^M$  do not occur. Let  $T_0$  be an  $\mathbb{I}_{\forall}$ -theory with countable models ( $L_{\mathbf{M}}$  is countable). Let  $\mathcal{C}$  be a category whose objects, which we call  $\mathcal{C}$ -models, are countable models of  $T_0$ . For ease of speaking we identify these models with the domain of their sort  $\mathbf{M}$ . The morphisms of  $\mathcal{C}$ , which we call  $\mathcal{C}$ -morphisms, are finite maps between  $\mathcal{C}$ -models.

- c1. the identity map  $\text{id}_A : M \rightarrow M$  is a  $\mathcal{C}$ -morphism, for any  $A \subseteq M$ ;
- c2.  $\mathcal{C}$ -morphisms are partial  $\mathbb{I}$ -embeddings;
- c3. the inverse of a  $\mathcal{C}$ -morphism is a  $\mathcal{C}$ -morphism;
- c3. if  $M$  is a  $\mathcal{C}$ -model and  $f : M \rightarrow N$  and  $\mathbb{I}$ -elementary map, then  $N$  is a  $\mathcal{C}$ -model and  $f$  is a  $\mathcal{C}$ -morphism.

We write  $M \leq N$  if the identity map  $\text{id}_M : M \rightarrow N$  is a  $\mathcal{C}$ -morphism. We also assume that  $\mathcal{C}$  is connected (c4) and that it has the amalgamation property (c5).

- c4. the empty map between two  $\mathcal{C}$ -models is a  $\mathcal{C}$ -morphism;
- c5. for every  $\mathcal{C}$ -morphism  $k : M \rightarrow N$  and every  $b \in M$  there is a  $\mathcal{C}$ -model  $N \geq M$  and a  $\mathcal{C}$ -morphism  $h : M \rightarrow N'$  that extends  $k$  and is defined on  $b$ .
